

Figure 1. Cohort assembly and analysis populations

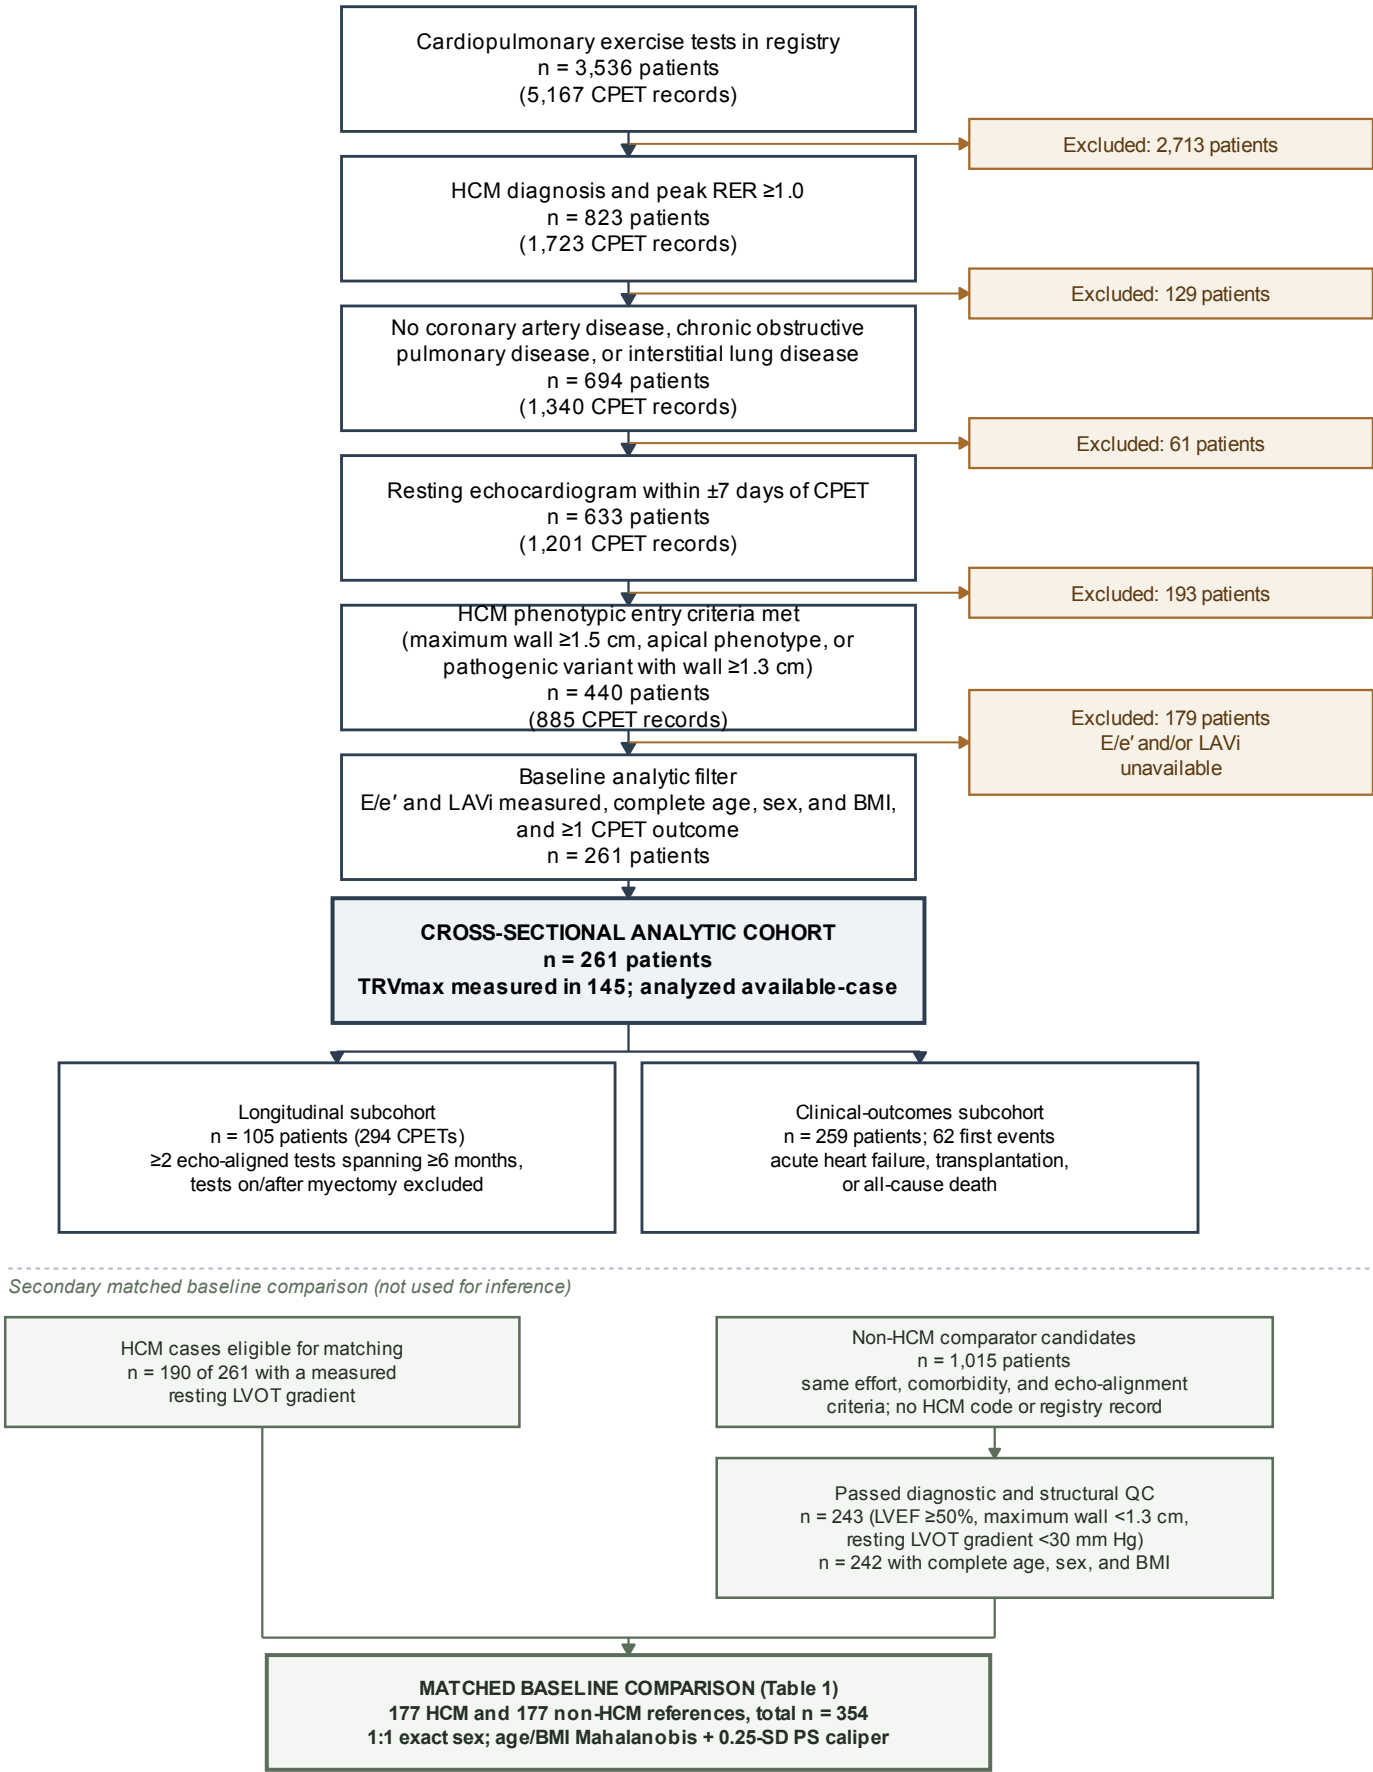

Figure 1. Cohort assembly and analysis populations. The vertical spine reports sequential HCM cohort entry, with exclusions at each step shown at right. The upstream E/e' and LAVi measurement-completeness requirement defines the cross-sectional analytic cohort, which is the parent population for the nested longitudinal and clinical-outcomes subcohorts. TRVmax is reported using its available-case denominator because requiring it would reduce the cohort further. The secondary matched baseline comparison joins HCM cases with a measured resting LVOT gradient to phenotypically screened non-HCM comparator candidates and supports Table 1 only. All counts are computed by the analysis pipeline at render time. CPET = cardiopulmonary exercise testing; LAVi = left atrial volume index; LVEF = left ventricular ejection fraction; LVOT = left ventricular outflow tract; QC = quality control; RER = respiratory exchange ratio; TRVmax = maximum tricuspid regurgitant velocity.
