

Crude vs. Adjusted Hazard Ratios

Supplemental Figure. Crude versus adjusted hazard ratios for non-significant Figure 5E predictors. Each panel shows the unadjusted (circle) and covariate-adjusted (diamond) hazard ratio per 1 SD for resting LVOT gradient, Peak $\dot{V}O_2$ per SD lower (FRIEND 2.0 % predicted), and $\dot{V}E/\dot{V}CO_2$ slope. Adjusted models include age, sex, and BMI as covariates. Horizontal lines represent 95% confidence intervals; the dashed vertical line marks HR = 1. Minimal change in point estimates between crude and adjusted models indicates that covariate adjustment does not account for the non-significant associations.
